## Abstract

We report results of an extended study of event-wise mean- $p_t$  fluctuations, charged-particle multiplicity fluctuations and multiplicity-mean  $p_t$  correlations for unidentified hadrons with respect to particle charge. From  $\langle p_t \rangle$  fluctuation studies we observe significant departures from a central-limit reference which suggest the presence of an isospin-dependent contribution to nonstatistical fluctuations. From charge-multiplicity studies we observe deviations from a central-limit reference consistent with resonance correlations but inconsistent with the substantial reduction of fluctuations predicted for rapid transition from a prehadronic state. We also observe significant multiplicity- $\langle p_t \rangle$  correlations which may provide information on local measure conservation and the remnants of initial-state scattering.
